Integrated Industrial Visual Inspection Scheme in Combination with Training and Inference

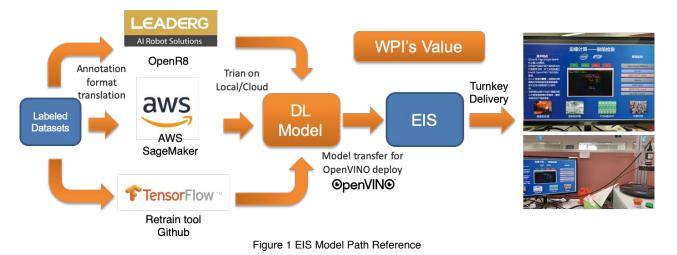

WPI Shares Integrated Industrial Visual Inspection Scheme in Combination with Training and Inference based on Intel® EIS

To meet the increasing demand for defect detection in the industrial field, Intel and WPI have jointly launched the "Training + Inference collaboratively Integrated Intel® EIS (Edge Insight Software) Industrial Visual Inspection Scheme". The system can be used to detect the defects of products with known types by using Balser camera, gateway and software application and supporting the acquisition of high-resolution images in combination with traditional vision, deep learning and vision algorithm. The product defect detection of aluminum parts in a well-known domestic factory is based on this framework as an example of application.

This scheme, based on computer vision, is to perform the operational processing of the acquired image data of an object through the special edge computing node device, and then to distribute the processed result:

- 1: Control the mechanical arm and give an alarm
- 2: Report the data to the edge server

The edge server collects data, processes and analyzes the data, and then completes the cloud connection.

1. Advantages of the Scheme

1.1 The overfitting degree of the recognition result is low

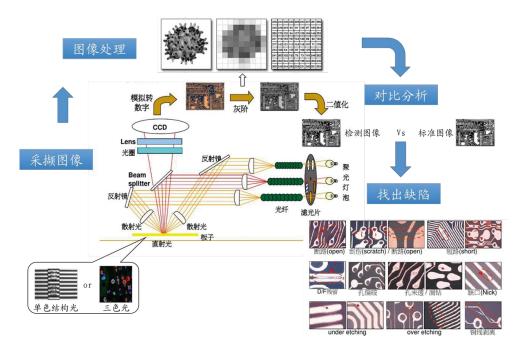

Figure 2 Schematic Diagram of Traditional AOI Defect Recognition Scheme

Because the traditional AOI scheme adopts the optical visual comparison analysis method to analyze the object to be inspected, the inspection overfitting rate is high, it is easy to misreport good products as defective products, so manual secondary screening is required at the backstage, which affects the production efficiency and increases the labor cost. At the same time, AOI defect recognition is based on the priori defect shape to make pattern recognition, and the defect types that can be classified itself are relatively limited, it cannot judge a problem, and then make a secondary classification.

This project bases on AI black box model for defect classification, at the same time, through the study of annotation of a large quantity of sample data, the defect target detection is automatically completed, the recognition accuracy is high, and the secondary review resources are reduced, at the same time, because the scheme uses deep learning technology, users do not need to match specific defect features, the statistics of all the features are completed automatically through artificial intelligence, so the number of defect classification can be greatly improved, compared with AOI, it can identify more subdivided defects.

1.2 Modular deployment

Usually, when an industrial project has been approved, because the application scenario varies, the system architecture often needs to be redesigned according to the project requirements, which greatly increases

Figure 3 OpenR8 Function Framework

the complexity and difficulty of the project deployment and consumes human resources. This scheme adopts the technology of Docker modular deployment, the step function tasks including data acquisition, integration, storage, analysis, algorithm deployment, message queue processing and so on are divided, and the underlying data logic is improved, thus the replicability of the system architecture is realized, so the system Integrator does not need to redesign the scheme architecture from beginning to end, as long as the selection of functional modules, parameter setting and model re-training are completed, the deployment of the whole scheme can be basically realized, which greatly reduces the difficulty of the project deployment and improves the reusability of the system.

1.3 Low training threshold

This project adopts LeaderG's OpenR8 graphical training tool, which has built in a variety of mainstream deep learning frameworks (Tensorflow, Caffe, Pytorch...) and algorithm models (SSD, MobileNet, GoogleNet...), users can easily create a deep learning model without mastering programming skills and by simply using the mouse through a simple browser interface.

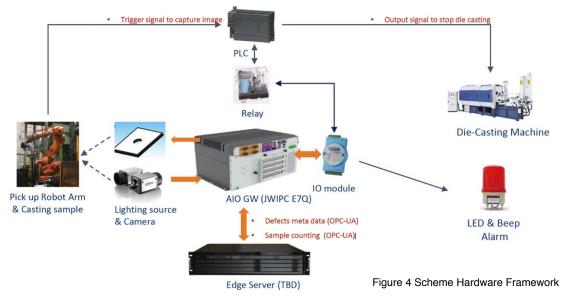

2. Application Cases

- Greige cloth defect detection real-time product quality inspection in the circular machine production workshop of
 the textile mill
- · Order tracking based on image recognition automatic order recognition of the garment factory
- · Metal surface defect detection product quality inspection of the aluminum die casting factory

3.System Configuration:

When a defective product is detected, the alarm indicator lights up. The operator shall check the product and system in detail, and press the reset button when confirming that there is no fault, the alarm indicator goes off.

3.1 Hardware scheme

3.1 Hardware scheme

The edge computing node of this scheme adopts the E7QL model developed by JWIPC (cooperative manufacturer) based on Intel Core Platform, which is specially designed for industrial fields. Some of its main features are as follows:

- The operating environment temperature is relatively wide, the operating temperature supports-20 to 60 degrees.
- · Fanless design avoids dust.
- The chipset Q170 adopted is a specialized industrial chip with good stability.
- Different CPU from i3 to i7 is provided to meet different computing power support. The top-end core i7 has strong computing power, 4 cores and 8 threads.
- Rich industrial interfaces, supporting a series of different interfaces, such as serial port, gigabit network card, GPIO, USB3.0 and MXM3.0, etc.
- Built-in PCIE expansion slot.
- · Modular design gives users different configuration choices.

3.2 Software solutions

Based on TICK time series processing architecture, this scheme realizes modular software design mode.

- · Telegraf data acquisition
- InfluxDB data reception and storage
- Chronograf data
 summary and presentation
- Kapacitor data processing, such as monitoring strategy

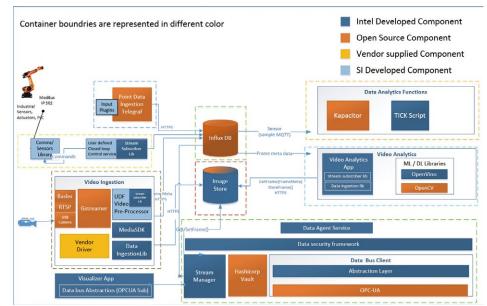

Figure 5 Scheme Software Framework

3.3 Prototype system

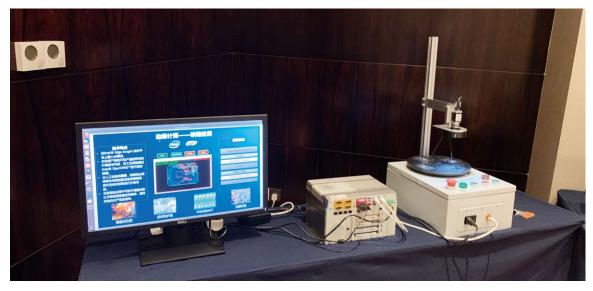

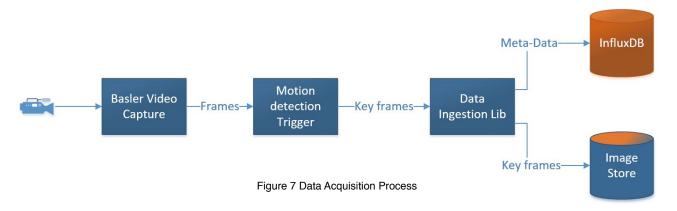

Figure 6 Scheme Prototype System Presentation

4 Key Technology

4.1 Key frame screening

In this scheme, OpenCV2 built-in algorithm is adopted to collect several positive bitmaps of the object to be inspected by setting the pixel point threshold, and the frame at the center of the picture is calculated and selected as the key frame of the object to be inspected for identification. At the same time, the meta data is extracted and transferred to the InfluxDB time series database.

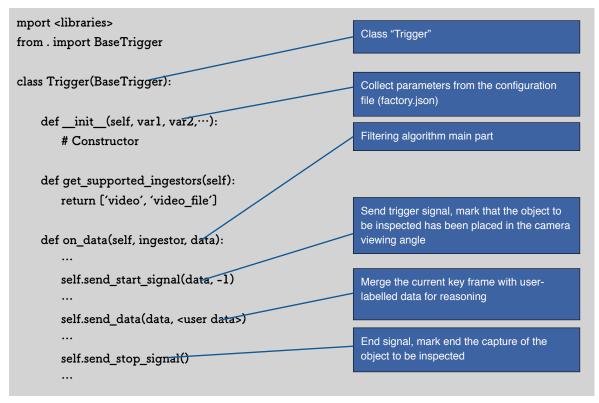

Figure 8 Key Frame Filtering Module Framework

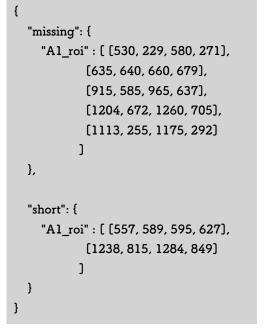

4.2 Image positioning

In this scheme, OpenCV2 FlannBasedMatcher module is adopted to match the key points of the key frame with the reference picture, so as to adjust the size and angle of the key frame. Meanwhile, findHomography module is used to calculate the similarity between the reference image and the key frame and judge the validity of the key frame (whether it is the object to be inspected), so as to identify it.

```
# Find matching keypoints
    raw_matches = self.flann.knnMatch(ref_des, img_des, k=2)
    for m in raw_matches:
       # Lowe's Ratio Test
      if len(m) == 2 and m[0].distance < m[1].distance * 0.7:
         matches.append(m[0])
    if len(matches) <= minMatches:
       self.log.debug("""Found less than minimum # of matches
                 required to overlay""")
       return None
    self.log.debug("Number of good matches: {}".format(len(matches)))
    src_pts = np.float32([ref_kp[m.queryIdx].pt for m
                 in matches]).reshape(-1, 1, 2)
    dst_pts = np.float32([img_kp[m.trainIdx].pt for m
                 in matches]).reshape(-1, 1, 2)
    # Calculate homography
    M, mask = cv2.findHomography(src_pts, dst_pts, cv2.RANSAC, 4.0)
    score = float(mask.sum()) / mask.size
    return (M, mask, score)
```

4.3 Classification recognition

First, mark the ROI area of the object to be inspected, intercept the image of the ROI area, send it to the pre-trained neural network model for classification analysis, so as to obtain the confidence data of defect types in the critical position of the object and make judgment.

4.4 Model training and deployment

The light weight model MobileNet_V2 based on Caffe framework is used for training, with low recognition delay and fast corresponding speed, which is very suitable for the production line with strict real-time requirements, the production line conveyor belt non-stop inspection can be realized.

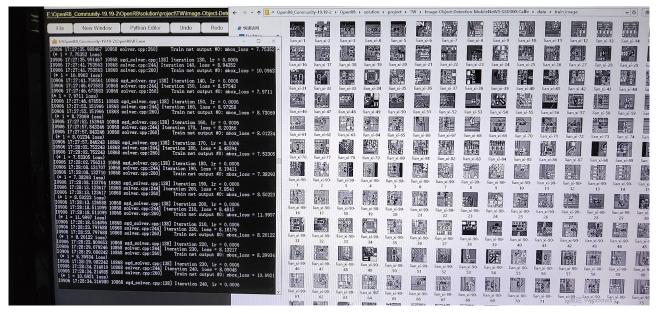

Figure 13 Data Annotation and Training

First convert the toolkit of Intel OpenVINO Model Optimizer to format files of .bin (Weight and Bias value) and .xml (model topology). Then, in connection with the model output data format, adjust the API interface calling method, present the detection result of ROI area identified on the prototype system, and push it to the background business logic. When a defective product is detected, the alarm indicator light lights up. The operator shall check the product and system in detail, and after confirming that there is no fault, press the reset button, and the alarm indicator light goes off.

About WPI Internet of Things solution aggregator

World Peace Industrial Group (WPI) is an aggregator of Intel ® Internet of Things solutions, and can provide the most diverse Intel ® Internet of Things solutions to meet your multi-field and multi-application business needs, which is the best channel in the industry. To play the role of Internet of Things solution aggregator, WPI has the ability to provide services for IT system aggregators and OT system aggregators in Asia and Greater China, to set up the bridge of overall end-to-end (edge-to-cloud) applications, to integrate networking solutions, to abandon industrial ODM/OEM/ISV solutions, to select appropriate solutions for system aggregators and to provide more effective support to inventory management. In addition, WPI assists in the establishment and development of industry knowledge and use cases, promotes the application of the Internet of Things, and supports the expansion of business through the collaborative work of ecosystem partners. As an aggregator of Intel ® Internet of Things solutions, we will use the technology partner ecosystem to provide customers with convergent, end-to-end and immediately deployed Intel ® industry overall solutions (Market Ready Solutions, MRS) and RFP Internet of Things development kits (RRK, RFP Ready Kits).
